REC'D 28 JUN 2004

WFO

PCT

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

Andrew Gervay

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

SURGICAL DEVICE

This invention relates to a surgical device and particularly relates to a device having two main components which are interconnected by a "snap-fit" connection.

BACKGROUND TO THE INVENTION

10 The goal of hip reconstruction is to attempt to reproduce the normal kinematics of the hip by recreating the functional geometry of the acetabulum and proximal femur. This greatly influences the outcome of the operation, restoring normal muscle
15 function, gait and ultimately the longevity of the implant.

In conventional replacement hip surgery a femoral component is inserted into the prepared femur. The
20 femoral component has a stem portion which projects into the femoral canal of the prepared femur and has an integral or separate modular head of substantially spherical shape. The ball-like head of the femoral component is received within an acetabular cup
25 component which is implanted in the patient's hip socket, ie the acetabulum. The acetabular cup has a substantially hemi-spherical bearing surface for movement of the ball head of the femoral component during action of the joint. The acetabular cup is
30 implanted into the prepared hip socket either with or without cement. Cementless types of acetabular cup may be secured in the prepared bone by a press fit or can be directly screwed in place or otherwise secured in place, for example by indirect means, eg by the use of

separate bone screws passing through apertures provided in the acetabular cup. Generally, the femoral stem is of metal and the ball head is of metal or of a ceramic material.

5
In some designs of hip prostheses the material of the bearing surface of the acetabular cup, is of the same material as that of the ball head, eg for a ceramic head a ceramic bearing surface is provided (a so-called
10 ceramic-on-ceramic prosthesis) and for a metal head a metal bearing surface is provided (a so-called metal-on-metal prosthesis). In some other designs, the acetabular bearing surface is of polyethylene and the acetabular cup is either provided with a polyethylene
15 inner liner or the acetabular cup is a single component made entirely from polyethylene.

The connection between the femoral stem and the femur may be cemented or cementless. Depending on which type
20 of connection is used, an appropriate broach and/or file is used to enlarge the femoral canal. For a cementless connection, the file is of substantially the same dimensions as the femoral stem which is to be implanted, whereas if the connection is cemented, the
25 file is slightly oversized relative to the femoral stem. Once the femoral canal has been enlarged sufficiently to accommodate it, the femoral stem is implanted. Then a series of trial femoral heads, which have bearing surfaces offset laterally and/or displaced
30 relative to the femoral stem to differing degrees, are attached to the femoral stem. This "trial reduction" procedure is used to select the most appropriate femoral head for a particular patient.

The applicant uses a modified procedure in which the broach or file itself, rather than the actual femoral stem, is used with a variety of trial femoral heads in a trial reduction procedure. This allows the surgeon
5 to assess stability of the joint and leg length, prior to selecting the definitive implant.

The surgeon has two methods of altering stability and leg length. A range of neck lengths are available for
10 the modular femoral head which can move the head centre either longer or shorter than the standard zero position, this will increase or decrease femoral offset and thus alter tissue tension, stability, but at the same time will also affect leg length. The second
15 method is to use an increased offset stem, which will increase tissue tension by lateralising the femur, without increasing leg length. With this system, both methods can be assessed at the trial reduction stage.

20 In all of these conventional techniques, the interconnection between the femoral head and the femoral stem (or the broach or file in the case of the applicant's existing procedure) comprises a pin formed on the femoral stem, file or broach and a corresponding
25 socket formed on the femoral head. This arrangement provides good lateral alignment, but does not prevent displacement of the femoral head along a longitudinal axis of the femoral stem, broach or file. This
"pistoning" effect makes it more difficult to select an
30 appropriate femoral head and tends to complicate the trial reduction procedure.

STATEMENTS OF INVENTION

According to a first aspect of the present invention there is provided a surgical device comprising a first
5 portion and a second portion, the first and second
portions being releasably connected together by means of cooperating first and second formations, the second formation comprising a resilient arm on the second
10 portion which engages the first formation on the first portion.

Preferably, the first formation is integrally formed with the first portion.

15 Preferably, the first formation comprises a recess or projection.

Preferably, the second formation is integrally formed with the second portion. It is particularly
20 advantageous to form the first formation integrally with the first portion and/or the second formation with the second portion, because the less components there are in a surgical tool, the easier it is to sterilise. Indeed, it will be appreciated that by forming the
25 cooperating formations integrally with the first and second portions, the number of separate components is reduced to a minimum and the surgical tool is particularly easy to sterilise.

30 Preferably, a recess or projection is formed on the resilient arm and engages the first formation. Preferably the recess or projection is formed at a free end of the resilient arm.

Preferably, the second portion is at least partially bifurcated.

5 Preferably, the resilient arm forms a fork of the bifurcated part of the second portion. Preferably, the first formation is received between forks of the bifurcated part of the second portion.

10 Preferably, the first portion is provided with a first planar guide surface which engages a second planar guide surface on the second portion.

15 Preferably, an abutment is provided, for example on the first or second planar guide surface, which abutment limits the relative movement between the first and second portions.

20 Preferably, the first portion is adapted to connect, one at a time, to a plurality of alternative second portions.

The surgical device may comprises a hip prosthesis for replacing a head of a femur. The first portion preferably comprises the stem of the prosthesis, and 25 the second portion is the same shape as a neck of the prosthesis. Preferably, the second portion is adapted to receive a prosthetic femoral head.

30 Alternatively, the first formation comprises a surgical tool. The second portion may comprise a detachable handle. Preferably, the first portion comprises a drill bit, broach, file or rasp.

Preferably, the first portion comprises an annular ridge formed around the circumference of the surgical tool. Preferably, the resilient arm is biased radially inwardly towards the surgical tool and may engage over
5 the ridge.

Preferably, the resilient arm is arcuate and curves at least partially around the circumference of the surgical tool.

10

A method of attaching a first portion of a surgical device to a second portion of a surgical device, the surgical device having the features of one or more of the preceding aspects of the present invention, the
15 first portion comprising an elongate member defining a longitudinal axis and the first formation being provided on a distal end of the first portion, the interconnection between the first and second formations being made by sliding the second portion towards the
20 first formation in a direction substantially perpendicular to the longitudinal axis of the first portion.

Preferably, the second portion comprises an adaptor to
25 which a plurality of alternative femoral heads can be connected. In an alternative embodiment, a plurality of adaptors of different lengths and/or shapes may be provided for use with alternative femoral heads, or a common femoral head, such that adjustment of the
30 femoral head relative to the femoral stem is provided by the adaptor, rather than, or as well as, by the femoral head itself.

BRIEF DESCRIPTION OF THE DRAWINGS

For a better understanding of the present invention,
 5 and to show more clearly how it may be carried into
 effect, reference will now be made, by way of example,
 to the accompanying drawings, in which:-

Figure 1 shows a femoral file, adaptor and trial
 10 femoral head in an assembled condition; and

Figure 2 shows an adaptor and trial femoral head in a
 disassembled condition.

15 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Figures 1 and 2 illustrate a surgical device comprising
 a femoral broach or file 2 comprising a file portion or
 stem 4 which tapers outwardly towards an enlarged
 20 fixing portion 6. An adaptor 8 is connected to the
 fixing portion 6 by means of cooperating formations 10,
 12. The adaptor 8 is provided with a shaft 14 which
 tapers towards a free end 16 of the adaptor 8. A trial
 femoral head 18, having a socket 20 which tapers
 25 inwardly towards its base, is received closely on the
 shaft 14.

A planar guide surface 22 is formed on the adaptor 8
 and rests on a corresponding planar guide surface 24
 30 formed on the fixing portion 6 of the femoral file 2.

The second formation 12 is integrally formed with the
 adaptor 8 and comprises a resilient arm having, at its
 free end, a projection 26. The adaptor 8 is bifurcated

at its end opposite to free end 16, such that the resilient arm comprises a first fork, and the portion 28 of the adaptor 8, on which is formed the planar guide surface 22, comprises the second fork. A recess 30 is defined between the resilient arm and the portion 28. An abutment 29 is formed on the adaptor 8 and projects into the recess 30.

The first formation 10 comprises a projection with a sloping leading surface 32 and a ridge 34 which is formed in an end surface of the fixing portion 6.

During an operation to install a prosthetic hip joint, the proximal end of the femur is prepared and the femoral canal is enlarged by means of the broach or file 2. When the broach or file is being used to enlarge the femoral canal a handle (not shown) is attached to the fixing portion 6.

When the required dimensions of the femoral canal have been achieved, the file 2 is left in place and the handle is detached. The adaptor 8 is then offered up to the file 2, such that the planar guide surface 22 rests on the planar guide surface 24 of the file 2 and the first formation 10 is received in a mouth of the recess 30. The adaptor 8 is then pushed in the direction A towards the first formation 10, so that the projection 26 rides up the leading surface 32 and drops into the ridge 34. At this instant, a leading edge of the first formation 10 comes into contact with the abutment 29, so that the adaptor 8 is firmly connected to the file 2. A trial reduction can then be carried out by offering up various trial femoral heads 18 have different offsets or having sockets 20 of different

depths until an appropriate femoral head has been selected.

Finally, the file 2 is removed from the femoral canal
5 and an appropriate femoral prosthesis is assembled with
the selected femoral head and implanted into the femur.

In an alternative embodiment not illustrated, a plurality of alternative trial adaptors 8 are provided,
10 which may for example have different lengths of shaft 14. An appropriate adaptor 8 may then be selected either for use with a common femoral head 18, or for use with one of a plurality of different femoral heads. During the trial reduction, the easy interconnection of
15 each adaptor 8 with the file 2, simply by means of pushing the cooperating formations 10, 12 together to make the connection and pulling them apart to break the connection, enables rapid selection of an appropriate adaptor.

20 It is readily apparent that as the formation 10 is integrally formed with the file 2 and the resilient arm 12 is integrally formed with the adaptor 8, the overall number of components are minimised and the surgical
25 device as a whole is very easy to sterilise.

The fixing portion 6 of the file 2 and the bifurcated region of the adaptor 8 can be made using a variety of known techniques. However, it has been found
30 particularly advantageous to cut these components from solid blocks of material using a hot wire cutter.

Various materials can be used to form the adaptor 8, such that the resilient arm 12 has sufficient

resilience to be repeatedly connected to and disconnected from the file 2. It had been thought that stainless steel would be insufficiently compliant and would fatigue excessively. However, the applicant has
5 discovered that Custom (registered trade mark) 455 stainless steel and Aubert & Duval X15TN stainless steel are particularly good materials for use with a surgical device in accordance with the present invention.

10

CLAIMS

1. A surgical device comprising a first portion and a second portion, the first and second portions being
5 releasably connected together by means of cooperating first and second formations, the first formation being attached to the first portion and the second formation comprising a resilient arm which is attached to the
10 second portion and engages the first formation on the first portion.
2. A surgical device as claimed in claim 1, in which the first formation is integrally formed with the first portion.
- 15 3. A surgical device as claimed in claim 1 or 2, in which the first formation comprises a recess or projection.
- 20 4. A surgical device as claimed in any one of the preceding claims, in which the second formation is integrally formed with the second portion.
5. A surgical device as claimed in any one of the
25 preceding claims, in which a recess or projection is formed on the resilient arm and engages the first formation.
- 30 6. A surgical device as claimed in claim 5, in which the recess or projection is formed at a free end of the resilient arm.

7. A surgical device as claimed in any one of the preceding claims, in which the second portion is at least partially bifurcated.

5 8. A surgical device as claimed in claim 7, in which the resilient arm forms a fork of the bifurcated part of the second portion.

9. A surgical device as claimed in claim 7 or 8, in which the first formation is received between forks of the bifurcated part of the second portion.

10. A surgical device as claimed in any one of the preceding claims, in which the first portion is provided with a first planar guide surface which engages a second planar guide surface on the second portion.

11. A surgical device as claimed in any one of the preceding claims, further comprising an abutment which limits the relative movement between the first and second portions.

12. A surgical device as claimed in any one of the preceding claims, in which the first portion is adapted to connected, one at a time, to a plurality of alternative second portions.

13. A surgical device as claimed in any one of the preceding claims, in which the first portion comprises a surgical tool.

14. A surgical tool as claimed in claim 13, in which the first portion comprises a drill bit, broach, file or rasp.

5 15. A surgical device as claimed in claim 13 or 14, in which the first formation comprises an annular ridge formed around the circumference of the surgical tool.

10 16. A surgical device as claimed in any one of claims 13 to 15, in which the resilient arm is arcuate and curves at least partially around the circumference of the surgical tool.

15 17. A surgical device as claimed in any one of the preceding claims, in which the second portion is a handle.

20 18. A surgical device as claimed in any one of claims 1 to 12, in which the second portion comprises an adaptor to which a femoral head can be connected.

25 19. A surgical device as claimed in claim 18, in which a plurality of adaptors of different lengths and/or shapes are provided for attachment to the first portion.

20. A surgical device substantially as described herein, with reference to and as shown in the accompanying drawings.

ABSTRACTSURGICAL DEVICE

A surgical device comprises a first portion 2 and a
5 second portion 8, the first and second portions 2, 8
being releasably connected together by means of
cooperating first and second formations 10, 12, the
first formation 10 being formed on the first portion 2,
and the second formation 12 comprising a resilient arm
10 which is formed on the second portion 8 and engages the
first formation on the first portion 2. Preferably,
the resilient arm is integrally formed with the second
portion.
